`nums[k-1]` (**0-indexed**). For example, `[0,1,2,4,5,6,7]` might be rotated at pivot index `3` and become `[4,5,6,7,0,1,2]`.

Given the array `nums` **after** the rotation and an integer `target`, return *the index of target if it is in `nums`, or `-1` if it is not in `nums`*.

You must write an algorithm with  $O(\log n)$  runtime complexity.

**Example 1:**

**Input:** `nums = [4,5,6,7,0,1,2]`, `target = 0`

**Output:** `4`

**Example 2:**

**Input:** `nums = [4,5,6,7,0,1,2]`, `target = 3`

**Output:** `-1`

**Example 3:**

**Input:** `nums = [1]`, `target = 0`

**Output:** `-1`

**Constraints:**

- $1 \leq \text{nums.length} \leq 5000$
- $-10^4 \leq \text{nums}[i] \leq 10^4$
- All values of `nums` are **unique**.
- `nums` is guaranteed to be rotated at some pivot.
- $-10^4 \leq \text{target} \leq 10^4$

28     return binSearch(nums, target, mid+1, high)
29 }

```

Testcase Run Code Result

Wrong Answer Run

Your input

`[4,5,6,7,0,1,2]`  
`0`

Output

`-1`  
`-1`

Expected

`4`  
`-1`
